

FPT UNIVERSITY  
COMPUTING FUNDAMENTALS

PE TRIAL #1

**PRF192 - PROGRAMMING FUNDAMENTALS**

Time Allowed: **60 minutes**

---

**INSTRUCTIONS**

1. This question paper contains **TEN (10)** questions.
2. The number of points for each question is in parentheses printed in left margin.
3. Maximum score of this question paper is **(10)** points.
4. Calculators are allowed, but not smart phones or tablets.
5. **No Other Materials** are allowed except the ones provided for you.
6. After the time allowed, you are required to submit your answers to the place provided for you.

———— **END OF INSTRUCTIONS** ————

- (1) 1. Users are required to enter two float variables **a** and **b** using the keyboard (STDIN). Compute the average square:

$$\frac{a^2 + b^2}{2}$$

then print out the result with 2 decimal places.

Below is an example of how the program will run:

```
1.23
4.56

OUTPUT:
11.15
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 2. Users are required to enter non-negative integer variables  $n$  using the keyboard (STDIN). The system displays the product of all even numbers that are greater than or equal to 2 and smaller than or equal to half of  $n$ . Below is an example of how the program will run when entering  $n = 9$ :

```
9
OUTPUT:
8
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 3. Your program allows users to enter 5 float numbers. The system displays the entered numbers in descending order.

Below is an example of how the program will run:

```
9.4
8.2
6.3
7.2
5.1

OUTPUT:
9.400000 8.200000 7.200000 6.300000 5.100000
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 4. Your program allows users to enter an integer number  $n$ . The system displays an inverted right triangle with the height equal  $n$ . Below is an example of how the program will run:

```
5
OUTPUT:
*****
****
***
**
*
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 5. Your program allows users to enter an array of  $n$  integers, where  $n$  is entered by the user and less than or equal 10. Your program should then print the sum of squared of all even integers.

**Hint:** It is possible to use `malloc()` to create a dynamic array.

Below is an example, in which number 5 is the value of  $n$  followed by 5 values of elements:

```
5
1
2
4
1
3

OUTPUT:
20
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 6. Your program allows users enter a long string **o** and a short string **p**. The system finds the occurrences of **p** in **o** and replaces them by the reversed of **p**. It then prints out the modified string **o**.

Below is an example:

```
ccbadeffgba
ba

OUTPUT:
ccabdefgab
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 7. Your program should allow users to find the two-digit number(s) that appear(s) **the most** in the array of 07 integers. Then your program should print out the found two-digit numbers.

Below are 03 examples to show how the program works:

**Example 1: One most appearing two-digit number**

```

1
3
5
7
12
12
12

OUTPUT:
12
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .

```

**Example 2: No two-digit number**

```

1
3
5
7
9
1
2

OUTPUT:
no two-digit number
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .

```

**Example 3: More than 01 most appearing two-digit numbers**

```
10
10
1
2
3
12
12

OUTPUT:
10 12
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 8. Your program should allow users to enter a character, then it should display the location of that character in the ASCII table and its octal format with 04 number places.

Example:

```
a
OUTPUT:
97 0141
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 9. Your program should allow users to enter a positive integer number  $n$ , compute the reversed number of  $n$  (called  $nrev$ ) then print out 02 values:  $nrev$  and  $n + nrev$ .

Example:

```
3089

OUTPUT:
9803 12892
-----
Process exited after 0.04649 seconds with return value 1701
Press any key to continue . . .
```

- (1) 10. Your program should allow users to enter an integer number  $n$ , then it should display 03 smallest prime numbers which are greater than  $n$   
Examples:

```
200  
  
OUTPUT:  
211, 223, 227  
-----  
Process exited after 0.04649 seconds with return value 1701  
Press any key to continue . . .
```

———— **END OF QUESTIONS** ————
